

# Exercise 9

Jiska Classen  
Tobias Volz

## H #9.1 CAN

a)

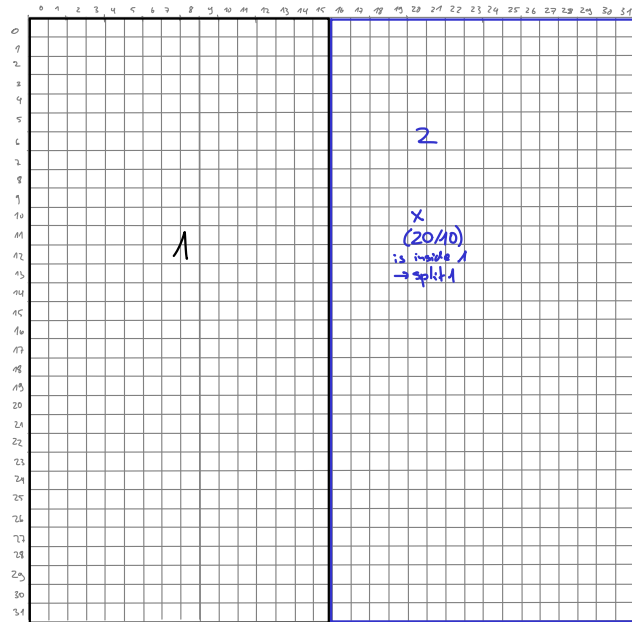

C3, 49f

### Scenario 1

$32^2$  identifier space  
node 1 joins

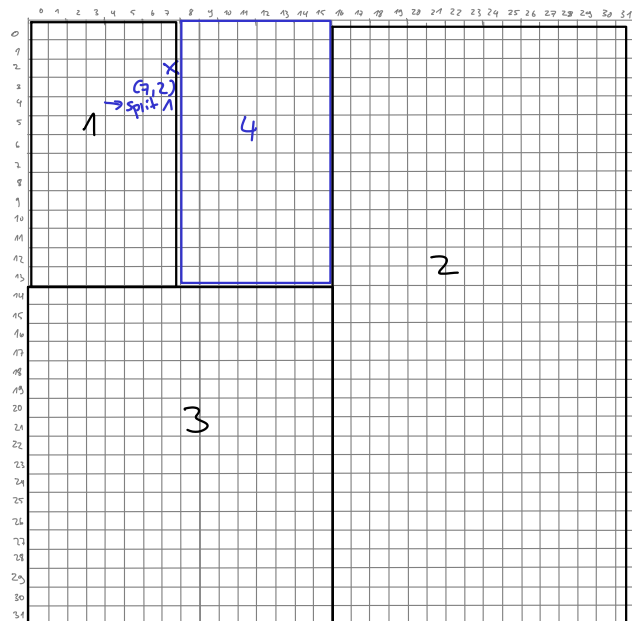

node 2 joins

node 3 joins

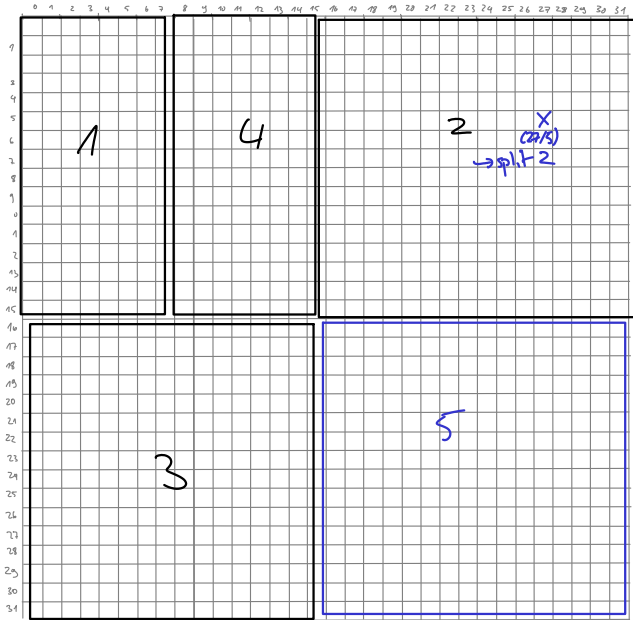

node 4 joins

... receives lower part of zone

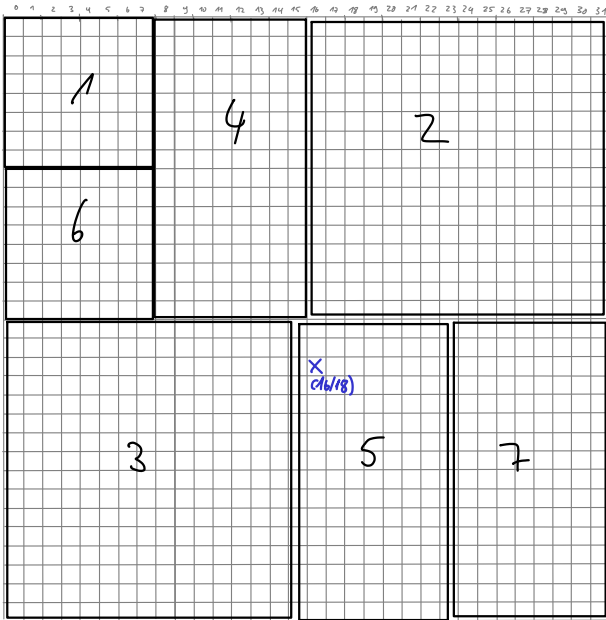

node 5 joins

node 6 joins

node 7 joins

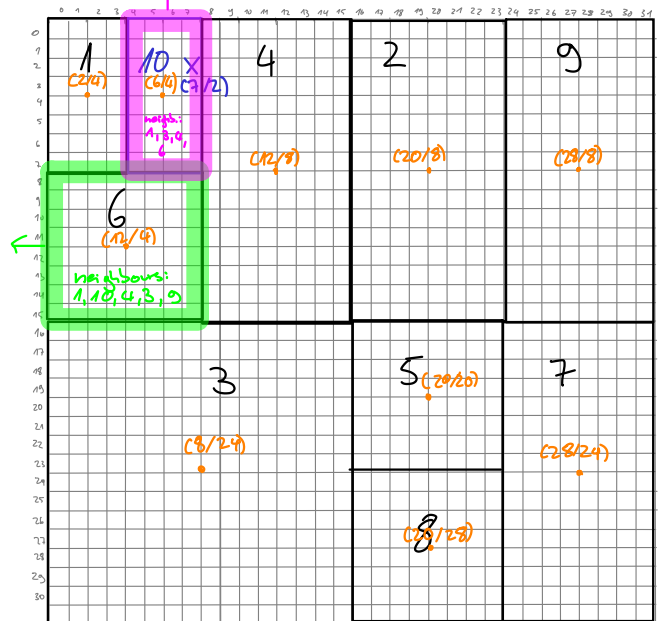

node 8 joins

node 9 joins

node 10 joins => result, new identifiers according to zone center

join of (7/2) again is possible since identifiers were reassigned to zone's center

Scenario 2

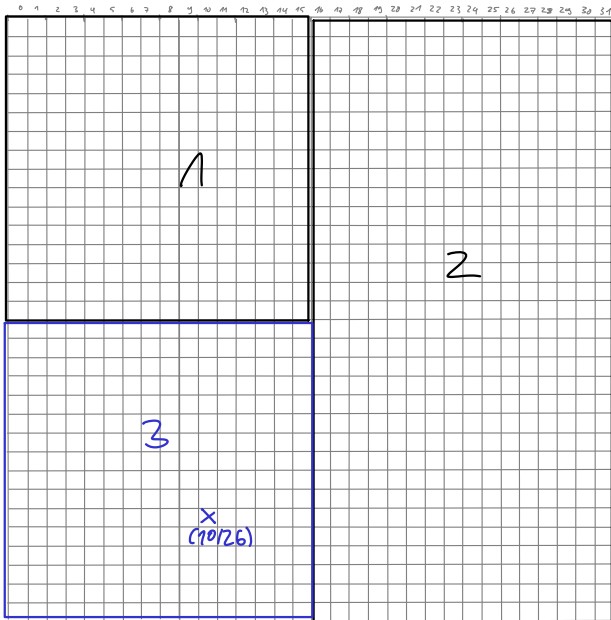

node 1 joins

node 2 joins

node 3 joins

node 4 joins

node 5 joins

node 6 joins

node 7 joins

node 8 joins

node 9 joins

node 10 joins → result

(a) normally it would be split like that:  
... and in next step:

assuming node 1 is taken over by 2 and node 3 is taken over by 4, the shown partitions are possible.

(meaning: node 2 is now responsible for the green area which actually consists of 2 partitions)  
also possible with additional joins/leaves

(b) if buckets were split like that:

... and node 5 took over node 2,  
and node 4 took over nodes 6 and 7, the resulting partitions are possible.  
also possible with additional joins/leaves

(d) is not possible! nodes are always split horizontal or vertical, only sth. like that would be possible (after many takeovers):

(c) if buckets were split like that:

... it would be normal, this scenario can be created without any takeover!

## H# 9.2 Pastry / Tapestry

### a) Routing Tables (Tapestry)

• neighbour tables (with largest node ID because we don't have ping times etc. to measure distance)

↳  
GfF.

• entries in level  $n$ :

- have a common prefix of  $n-1$  digits
- one entry per digit is possible
- the entry's digit is on position  $n$
- the rest of the digits is chosen so that the neighbour is as close as possible

node 1ef1

Level 1 empty here since nodes are on lower levels

Entry \ Level	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
1	0be4	<del>1ef1</del>	2ed6	3cfa	4bcb	5f7d	6f6	7821	8d96	9dc0	Af55	B40	ce63	ded9	E	F51
2	<del>0</del>	<del>1</del>	12e4	<del>3</del>	1494	<del>5</del>	<del>6</del>	<del>7</del>	<del>8</del>	<del>9</del>	<del>A</del>	<del>B</del>	<del>C</del>	<del>D</del>	<del>E</del>	1Fc0
3	<del>0</del>	<del>1</del>	<del>2</del>	<del>3</del>	<del>4</del>	<del>5</del>	<del>6</del>	<del>7</del>	<del>8</del>	<del>9</del>	<del>A</del>	<del>B</del>	<del>C</del>	<del>D</del>	<del>E</del>	<del>F</del>
4	<del>0</del>	1ef1 node itself	<del>2</del>	<del>3</del>	<del>4</del>	<del>5</del>	<del>6</del>	<del>7</del>	<del>8</del>	<del>9</del>	<del>A</del>	<del>B</del>	<del>C</del>	<del>D</del>	<del>E</del>	<del>F</del>

empty, node doesn't exist

node 6f65

Entry \ Level	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
1	0bef	1ef1	2edb	3cfa	4bcb	5f7d	<del>6</del>	<del>7</del>	8d96	9dc0	Af58	B5ef	ce63	DD9	E	F51
2	<del>0</del>	<del>1</del>	<del>2</del>	<del>3</del>	<del>4</del>	<del>5</del>	<del>6</del>	<del>7</del>	<del>8</del>	<del>9</del>	6A18	<del>B</del>	<del>C</del>	<del>D</del>	<del>E</del>	<del>F</del>
3	6feb	<del>7</del>	<del>8</del>	<del>9</del>	<del>A</del>	<del>B</del>	<del>C</del>	<del>D</del>	<del>E</del>	<del>F</del>	<del>A</del>	<del>B</del>	<del>C</del>	<del>D</del>	<del>E</del>	<del>F</del>
4	<del>0</del>	<del>1</del>	<del>2</del>	<del>3</del>	<del>4</del>	<del>5</del>	<del>6</del>	<del>7</del>	<del>8</del>	<del>9</del>	<del>A</del>	<del>B</del>	<del>C</del>	<del>D</del>	<del>E</del>	<del>F</del>

### 6) leaf nodes (Pastry)

Source of how Pastry routing and routing tables work: Paper "Pastry: Scalable, decentralized object location and routing for large-scale peer-to-peer systems" by A. Rowstron and P. Druschel

Leaf set for  $L=4 \rightarrow$  2 smaller and 2 larger nodes

- for node 1ef1

- smaller: 12e4, 1494

- larger: 1fc0, 21c4

- for node 6f65

- smaller: 6a18, 6f06

- larger: 7457, 74c0

- o failing nodes are in a row

### c) Rating (Pastry)

from 1ef1 to 6f0b

- 1ef1 - compares 6f0b to leaf nodes → negative
  - compares 6f0b to its routing table (from level 4 to 1) and finds 6f65
  - routes message to 6f65
- 6f65 - compares 6f0b to leaf nodes → positive
  - routes message to 6f0b
- 6f0b - processes the message

### d) Back-up Nodes (Tapestry, Chord, KAD)

KAD doesn't implement backup nodes for routing table entries because it is querying multiple contacts in each step. It's possible to find a target in KAD even if a node on one possible route is down because there are still other contacts left.

After a failure of a node in Chord, the successor becomes responsible for that node's area. ⇒ The successor should be chosen as backup.

Finger entries pointing to the failure node become invalid. If a node is nearer (less hops...) to the failing node, it's probability of having a finger to the failing node is higher.  
⇒ the predecessor's predecessor should be chosen as 2nd backup.

(it is not the predecessor and successor as in exercise b) because the chord ring isn't bidirectional)
